Abstract

In this paper we present *MGtoolkit*: an open-source Python package for implementing metagraphs - a first of its kind. Metagraphs are commonly used to specify and analyse business and computer-network policies alike. *MGtoolkit* can help verify such policies and promotes learning and experimentation with metagraphs. The package currently provides purely textual output for visualising metagraphs and their analysis results.

Keywords: metagraph implementation, computer-network policy, policy analysis

1. Motivation

2 A metagraph is a generalised graph theoretic structure that has sev-
3 eral useful applications. They are commonly used to construct and analyse
4 business policies in decision-support systems and workflow-management sys-
5 tems [1]. Metagraphs are also useful to analyse, optimise and troubleshoot
6 communication-network policies [2].

7 A metagraph is a directed graph between a collection of sets of ‘atomic’
8 elements. Each set is a node in the graph and each directed edge represents
9 the relationship between the sets. A simple example is given in Figure 1(a)
10 where multiple sets of users (U_1, U_2, U_3) are related to sets of network re-
11 sources (R_1, R_2) by the directed edges e_1, e_2 and e_3 which describes which
12 user u_i is allowed to access resource r_j .

13 In this paper we describe an off-the-shelf tool for implementing meta-
14 graphs – *MGtoolkit* – implemented in Python. At the time of writing, we
15 are aware of one other metagraph API- ‘Haskell library for metagraph data
16 structure’ [3]. This library is being developed in the Haskell programming
17 language but is not complete as far as we can determine.

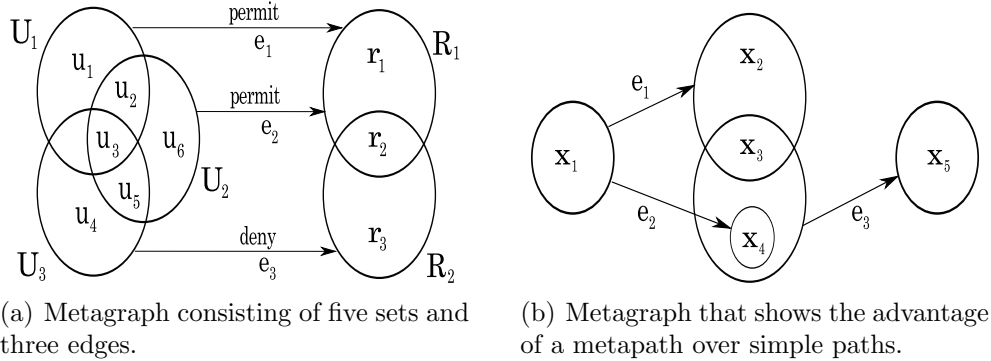

Figure 1: Metagraph examples.

18 Developing a metagraph tool faces several key challenges. For instance,
 19 a metagraph does not use simple edge weights in its adjacency matrix. Also
 20 metagraphs admit representations other than those used for simple graphs,
 21 but as in simple graphs, the representation is important for certain algo-
 22 rithms. In addition, there are many operations defined on a metagraph that
 23 must be supported by such a tool. These operations help analyse useful
 24 properties such as connectivity, redundancy and allow metagraph transfor-
 25 mations, but go beyond standard graph operators.

26 Metagraphs have many uses in general. One in particular is in specifying
 27 and analysing communication-network policies. We will demonstrate the use
 28 of metagraphs here by taking access-control policies in a computer network
 29 as an example. But, metagraphs can be equally used in other policy contexts
 30 (*e.g.*, QoS, network-service chaining, traffic measurement *etc.*).

31 2. Background

32 The formal structure of a metagraph can be defined as follows:

33 **Definition 1** (Metagraph). *A metagraph $S = \langle X, E \rangle$ is a graphical construct*
 34 *specified by a generating set X and a set of edges E defined on X . A generat-*
 35 *ing set is a set of variables $X = \{x_1, x_2, \dots, x_n\}$ and an edge $e \in E$ is a pair*
 36 *$e = \langle V_e, W_e \rangle$ such that $V_e \subset X$ is the invertex and $W_e \subset X$ is the outvertex.*

37 This definition is similar to that of a directed hypergraph, but in addition
 38 metagraphs have several useful operators and properties. One in particular
 39 is the notion of a *metapath* [1] which describes connectivity between sets of
 40 elements in a metagraph, but is somewhat different from a path in a graph.

41 **Definition 2** (Metapath). *A metapath from source $B \subset X$ to target $C \subset X$*
 42 *in a metagraph $S = \langle X, E \rangle$ is set of edges E' such that every $e' \in E'$ is on a*

43 path from an element in B to an element in C . In addition $[\bigcup_{e'} V_{e'} \setminus \bigcup_{e'} W_{e'}] \subseteq$
44 B and $C \subseteq \bigcup_{e'} W_{e'}$.

45 A metapath is more useful than a simple path (*i.e.*, a sequence of edges).
46 Figure 1(b) illustrates this using two simple paths from x_1 to x_5 : (e_1, e_3)
47 and (e_2, e_3) . Element x_1 can reach x_5 without knowing anything about
48 the intermediate nodes x_2, x_3, x_4 if all three edges e_1, e_2, e_3 are used but the
49 simple paths do not capture this fact. But, $\{e_1, e_2, e_3\}$ does not represent
50 a simple path; there is no sequence of connected edges consisting of these
51 edges. Rather, this metapath is the union of edges in two simple paths.

52 Reachability between a source node and a target node can be determined
53 by finding valid metapaths between the two in a metagraph [1] (*e.g.*, the
54 metapath from x_1 to x_5 in Figure 1(b) is $\{e_1, e_2, e_3\}$).

55 Metagraphs have a property called *dominance* which allows to determine
56 whether a metapath has any redundant components (edges or elements) [1].
57 A metapath is *input-dominant* if no proper subset of its source connects to the
58 target; *edge-dominant* if no proper subset of its edges is also a metapath from
59 the source to the target; and *dominant* if it is both input- and edge-dominant
60 [1]. Non-dominant metapaths indicate redundancies in a metagraph and
61 hence, redundancies in the policies depicted by the metagraph.

62 In metagraph theory, the notion of cutsets and bridges allow one to lo-
63 cate edges that are critical [1]. A *cutset* is a set of edges which if removed,
64 eliminates all metapaths between a given source and a target. A singleton
65 cutset is a *bridge*. In an access-control policy context for instance, bridges
66 and cutsets indicate if there exists a critical policy or a policy set that enable
67 access between certain users and resources.

68 It is also possible to derive a projection for a given metagraph. A projec-
69 tion is a simplified metagraph that provides a high-level view of the original
70 metagraph by concealing certain details [1]. In a complex metagraph with
71 many edges, a projection helps to visualise the important aspects with clarity
72 and ease. For instance, in a complex access-control policy with many rules,
73 projections help administrators visualise connectivity between a subset of
74 users and resources.

75 Metagraphs can have attributes associated with their edges. One such at-
76 tributed metagraph is a *conditional metagraph* [1]. A conditional metagraph
77 includes propositions – statements that may be true or false – assigned to
78 their edges as qualitative attributes [1]. The generating set of these meta-
79 graphs are partitioned into a variables set and a propositions set.

80 Conditional metagraphs are particularly useful in specifying access-control
81 policies because they allow a policy (such as permit user u_1 to access resource
82 r_1) to be activated conditionally (*e.g.*, during business hours only).

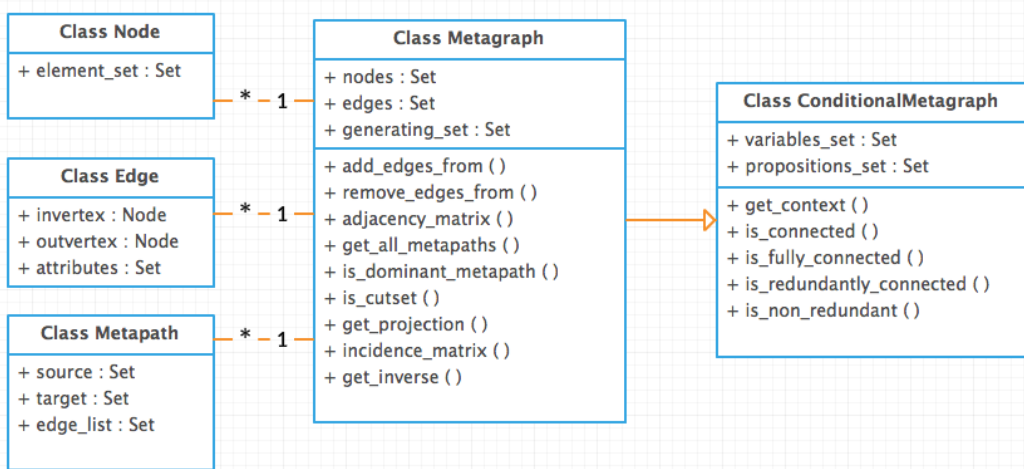

Figure 2: *MGtoolkit* entity relationship model (*-1 denotes a many-to-one relationship and \rightarrow denotes an extension).

83 3. Overview of *MGtoolkit*

84 *MGtoolkit* is implemented solely in Python 2.7 which is an interpreted,
 85 object-oriented, open-source language. Python has a concise but natural
 86 syntax for many of its data types, which makes programs exceedingly clear
 87 and easy to read; as the saying goes, ‘Python is executable pseudocode.’ De-
 88 pendencies of *MGtoolkit* include the packages NumPy 1.9 and NetworkX 1.7;
 89 both very popular and stable open source Python packages.

90 Figure 2 depicts the entity model we have employed in the underlying
 91 framework. Some attributes have been omitted in the *Metagraph* entity for
 92 simplicity.

93 A *Metagraph* entity consists of a set of *Node* entities and a set of *Edge*
 94 entities. Each *Node* contains a subset of elements from the metagraph’s gen-
 95 erating set. An *Edge* has the members: `invertex` and `outvertex`, assigned
 96 a *Node* each, and an `attributes` member that returns any edge attributes.

97 A *Metagraph* entity also has the methods: `add_edges_from()` and
 98 `remove_edges_from()`, to add and delete edges as necessary. In addition, the
 99 entity includes methods to derive its adjacency matrix, find metapaths, check
 100 metapath properties (e.g., `is_dominant_metapath()`) and edge properties
 101 (e.g., `is_cutset()`).

102 The `source` and `target` members of a *Metapath* return subsets of ele-
 103 ments in a metagraph’s generating set. The `edge_list` member returns an
 104 edge set between the `source` and `target` which satisfy Definition 2.

105 A *ConditionalMetagraph* entity extends a *Metagraph* and supports propo-
 106 sition attributes in addition to variables. A *ConditionalMetagraph* inherits

Listing 1: *MGtoolkit* implementation of policy in Figure 1(a).

```

1 # define policy metagraph
2 variable_set = {'u1', 'u2', 'u3', 'u4', 'u5', 'u6', 'r1', 'r2', 'r3'}
3 propositions_set = {'action=permit', 'action=deny'}
4 cm = ConditionalMetagraph(variable_set, propositions_set)
5 cm.add_edges_from([
6     Edge({'u1', 'u2', 'u3'}, {'r1', 'r2'}, attributes=['action=permit']),
7     Edge({'u3', 'u4', 'u5'}, {'r2', 'r3'}, attributes=['action=deny']),
8     Edge({'u2', 'u3', 'u5', 'u6'}, {'r1', 'r2'}, attributes=['action=permit'])])
9
10 # compute redundancies and conflicts
11 all_metapaths = cm.get_all_metapaths()
12 for metapath in all_metapaths:
13     if cm.has_redundancies(metapath):
14         print('redundancy detected: %s'%repr(metapath))
15     if cm.has_conflicts(metapath):
16         print('conflict detected: %s'%repr(metapath))

```

Listing 2: Partial output from running code in Listing 1.

```

1 conflict detected: Metapath({ Edge(set(['u1', 'u2', 'u3', 'action=permit']),
    set(['r1', 'r2']))), Edge({'u3', 'u4', 'u5'}, {'r2', 'r3'}, attributes=['
    action=deny'])})

```

107 the base properties and methods of a `Metagraph` and additionally supports
108 methods to derive its context metagraphs (*i.e.*, `get_context()`), check con-
109 nectivity properties (*e.g.*, `is_fully_connected()`) and redundancy proper-
110 ties (*e.g.*, `is_non_redundant()`).

111 The code snippet in Listing 1 instantiates the example access-control
112 policy in Figure 1(a) using *MGtoolkit* and then checks policy consistency.
113 It returns a redundancy and two conflicts—one is shown in Listing 2. The
114 redundancy is due to e_1 and e_3 both enabling access to R_1 from u_2 and u_3 .
115 The conflicts stem from e_3 denying access to R_2 . More detailed examples
116 based on business policies and workflows can be found on pages 81, 109 and
117 126 of the metagraph text [1].

118 4. Impact and challenges

119 There are many packages available for analysing graphs, *e.g.*, `igraph`, `Net-`
120 `workX`, `Gephi` [4, 5, 6]. These are being increasingly utilised. Metagraphs
121 provide a powerful generalisation of simple graphs and are particularly suit-
122 able for modeling business and computer-network policies [1, 2].

123 *MGtoolkit* is the first publicly available Python API for implementing
124 metagraphs. It serves two key purposes. Firstly, the API allows users to
125 learn about metagraphs in an interactive manner by creating metagraph
126 examples, applying metagraph operations and evaluating the results. The
127 documentation and tutorials associated with the package simplify the learn-
128 ing curve. Secondly, the API is a building block for developing and analysing
129 metagraph-based applications such as decision-support systems. Developers
130 can harness the advantages and power of metagraphs in to their applications
131 by simply importing *MGtoolkit*.

132 We believe our API is a first step to revisit old questions and tackle
133 new challenges. For instance, in the specification and analysis of computer
134 network policies: current approaches either lack high-level specification ca-
135 pability or formal semantics. *MGtoolkit* is a gateway to harness the best of
136 both of these worlds.

137 We have used the GitHub open source code hosting and development
138 platform to enable user collaboration.

139 A key drawback in developing *MGtoolkit* was the fact that the only meta-
140 graph text available for reference contained several discrepancies. For in-
141 stance, the inverse metagraph generation algorithm given in the text failed
142 to replicate the example output provided (Figure 4.9 on page 47 in [1]). Upon
143 clarification with the author, we found that the example was in fact incorrect.

144 Also several metapath examples given contradicted the definition of a
145 metapath (*e.g.*, metapath M_4 on page 28 in [1]). We strictly adhered to the
146 definition because the formal metagraph properties derived were based on
147 the definition.

148 5. Conclusions and future work

149 In this paper, we present *MGtoolkit*: an open-source Python package for
150 implementing metagraphs. The software promotes learning and experimenta-
151 tion with metagraphs and can help analyse business- and computer-network
152 policies alike.

153 In the future, we are planning several applications based on *MGtoolkit*,
154 one in particular is a tool for the formal analysis of computer-network policies.
155 Additionally, some of the algorithms suggested in [1] are not efficient and we
156 plan to improve on them.
